

i The contrast separates the models; the levels do not

Panels a-h show LEVELS: the reported model's IPS and vertex curves against the design's own cells, and the count in each panel is how many of those 68 observed proportions fall inside their own interval.

Panel i counts something else — the paired IPS – vertex CONTRAST, computed per posterior draw, over the 34 cells that contrast defines. The two denominators are not the same. No cell is binned, ranked or chosen post hoc.
